 - Extended via packages
- RStudio is an integrated development environment for R, which includes:
 - a console to run R code
 - an editor to write code and text
 - tools for plotting, history, debugging and workspace management
- Let's open RStudio and a plain R Script

Running R code and operators

```
# Arithmetic Operators
1 + 1
## [1] 2
2 * 8
## [1] 16
9 / 3
## [1] 3
2^3
## [1] 8
```

Running R code and operators

```
# Relational Operators
10 > 8
## [1] TRUE
7 <= 6
## [1] FALSE
(2 * 5) == 10
## [1] TRUE
1 != 2
## [1] TRUE
```

Objects in R: vectors and assignment

[1] TRUE FALSE FALSE

```
# Concatenate vectors into a new vector
c(1, 2, 3)
## [1] 1 2 3
# Assign them to a new object for manipulation
x \leftarrow c(1, 2, 3)
print(x) # or simply, x
## [1] 1 2 3
# Operators on vector
x + 1
## [1] 2 3 4
x == 1
```

Objects in R: vectors and functions

```
# Use an object as input to a function
x \leftarrow c(1, 2, 3)
class(x)
## [1] "numeric"
length(x)
## [1] 3
mean(x)
## [1] 2
```

Objects in R: three beginner tips

1. Unless you assign (<-) some operations or transformations to an object, those chances will not be registered

```
x \leftarrow c(1, 2, 3)
print(x + 1)
## [1] 2 3 4
print(x)
## [1] 1 2 3
x < -x + 1
print(x)
## [1] 2 3 4
```

Objects in R: three beginner tips

New assignment will overwrite the original values if you assign some values to an existing object. It is a major source of errors. One advise is to keep distinct object names

```
x <- c(1, 2, 3)
length(x)

## [1] 3

x <- c(1, 2, 3, 4, 5)
length(x)

## [1] 5</pre>
```

Objects in R: three beginner tips

[1] 2

3. When using functions, we often bump into unexpected outputs, or error messages:

```
y < -c(1, 2, 3, NA)
mean(y)
## [1] NA
# It's essential to know how to seek help:
help(mean)
?mean
# Specify appropriate arguments for functions:
mean(y, na.rm = TRUE)
```

▶ What are vectors exactly?

- ► What are vectors exactly?
 - ► (Atomic) vectors are the most basic units of data in R

- What are vectors exactly?
 - (Atomic) vectors are the most basic units of data in R
 - Most common types of atomic vectors: numeric (integer, double), logical, character

[1] "character"

Most common types of atomic vectors: numeric (integer, double), logical, character

```
x \leftarrow c(1, 2, 3)
class(x)
## [1] "numeric"
y <- c(TRUE, FALSE, FALSE)
class(y)
## [1] "logical"
names <- c("Peter", "Paul", "Mary")</pre>
class(names)
```

You can also coerce one type of vector into another:

```
x <- c(1, 2, 3)
x <- as.character(x)

print(x)

## [1] "1" "2" "3"

class(x)</pre>
```

```
## [1] "character"
```

Objects in R: matrix and data frame

► To deal with massive data, we need efficient data structures to store and manipulate vectors: **matrices** and **data frames**

To create a matrix:

```
# Create a vector
numbers <-1:19
print(numbers)
## [1] 1 2 3 4 5 6 7 8 9 10 11 12
# Store it as a matrix
matrix1 <- matrix(data = numbers, nrow = 3, byrow = TRUE)
print(matrix1)
##
      [,1] [,2] [,3] [,4]
```

```
## [1,1] [,2] [,3] [,4]
## [1,] 1 2 3 4
## [2,] 5 6 7 8
## [3,] 9 10 11 12
```

```
# Basic information
class(matrix1)

## [1] "matrix" "array"

dim(matrix1) # dimensions

## [1] 3 4
```

```
# We can change the row/column names of matrices
rownames(matrix1)
## NUI.I.
rownames(matrix1) <- c("row1", "row2", "row3")</pre>
print(matrix1)
## [,1] [,2] [,3] [,4]
## row1 1 2 3
## row2 5 6 7 8
## row3 9 10 11 12
```

row1

row2

row3

```
# Automate any repetitive process
col_names <- paste0("column", 1:4)
print(col_names)

## [1] "column1" "column2" "column3" "column4"

colnames(matrix1) <- col_names
print(matrix1)</pre>
```

3

11

column1 column2 column3 column4

2

6

10

5

```
# To augment the matrix with new column
column5 <- c(13, 14, 15)
matrix1 <- cbind(matrix1, column5)
print(matrix1)</pre>
```

##		column1	column2	column3	column4	column5
##	row1	1	2	3	4	13
##	row2	5	6	7	8	14
##	row3	9	10	11	12	15

```
# To augment the matrix with new row
row4 <- c("a", "b", "c", "d", "e")
matrix1 <- rbind(matrix1, row4)
print(matrix1)</pre>
```

```
##
       column1 column2 column3 column4 column5
                      "3"
                             "4"
## row1 "1"
              "2"
                                     "13"
              "6"
                      "7"
                             "8"
                                    "14"
## row2 "5"
              "10"
                      "11" "12" "15"
## row3 "9"
              "b"
                      "c"
                             "d"
                                     "e"
## row4 "a"
```

Why do all vectors become characters?

Matrices vs. data frames

- Matrices vs. data frames
 - ► Matrices can only contain one **homogenous** type of vectors

- Matrices vs. data frames
 - Matrices can only contain one homogenous type of vectors
 - ▶ Data frames can contain **heterogeneous** types of vectors, and thus are more flexible

Data frames can contain **heterogeneous** types of vectors, and thus are more flexible

```
df1 <- data.frame(
  names = c("Peter", "Paul", "Mary"),
  age = c(14, 15, 16),
  female = c(FALSE, FALSE, TRUE),
  stringsAsFactors = FALSE
)
print(df1)</pre>
```

```
## names age female
## 1 Peter 14 FALSE
## 2 Paul 15 FALSE
## 3 Mary 16 TRUE
```

```
# Basic information
class(df1)
## [1] "data.frame"
dim(df1)
## [1] 3 3
str(df1)
   'data.frame': 3 obs. of 3 variables:
##
   $ names : chr "Peter" "Paul" "Mary"
   $ age : num 14 15 16
##
   $ female: logi FALSE FALSE TRUE
##
```

Objects in R: subsetting data

[1] "Peter" "Paul" "Mary"

► There are several ways to subset data: row/column indices, variable names, or evaluations

```
# 1) Subsetting by row/column indices
# For the element in row 1, column 1
df1[1, 1]
## [1] "Peter"
# For all elements in row 1, regardless of columns
df1[1,]
## names age female
## 1 Peter 14 FALSE
# For all elements in column 1, regardless of rows
df1[, 1]
```

Objects in R: subsetting data

```
# 2) Subsetting by variable names
df1$names
## [1] "Peter" "Paul" "Mary"
df1$age
## [1] 14 15 16
df1$female
## [1] FALSE FALSE TRUE
```

Objects in R: subsetting data

1 Peter 14 FALSE ## 2 Paul 15 FALSE

```
# 3) Subsetting by evaluations
df1[df1$age >= 15, ]
## names age female
## 2 Paul 15 FALSE
## 3 Mary 16 TRUE
df1[df1$female == TRUE, ]
## names age female
## 3 Mary 16 TRUE
df1[df1$name %in% c("Peter", "Paul"), ]
## names age female
```

Objects in R: creating new variable in data frame

```
print(df1)
##
    names age female
## 1 Peter 14 FALSE
## 2 Paul 15 FALSE
## 3 Mary 16 TRUE
df1$edu
## NULL
df1$edu <- c("hs", "col", "phd")
print(df1)
##
    names age female edu
## 1 Peter 14 FALSE hs
## 2 Paul 15 FALSE col
## 3
     Mary 16 TRUE phd
```

Summary of data structures in R

	Homogeneous	Heterogeneous
1d	Atomic vector	List
2d	Matrix	Data frame
nd	Array	

Another important data structure: factor for categorical data, which will be important for visualization purpose

► Create the following objects:

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}
 - ► Hint: break downs the question into two parts; check out function rep(..., times = ..., each = ...)

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}
 - ► Hint: break downs the question into two parts; check out function rep(..., times = ..., each = ...)
- 2. vector2: The sequence from 1 to 49 by an increment of 2

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}
 - Hint: break downs the question into two parts; check out function rep(..., times = ..., each = ...)
- 2. vector2: The sequence from 1 to 49 by an increment of 2
 - Hint: check out function seq(...)

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}
 - ► Hint: break downs the question into two parts; check out function rep(..., times = ..., each = ...)
- 2. vector2: The sequence from 1 to 49 by an increment of 2
 - Hint: check out function seq(...)
 - ▶ Subset the 3rd, 16th, and 25th elements of the vector

- Create the following objects:
- 1. vector1: {a1, a2, a3, b1, b2, b3, c1, c2, c3 ... z1, z2, z3}
 - Hint: break downs the question into two parts; check out function rep(..., times = ..., each = ...)
- 2. vector2: The sequence from 1 to 49 by an increment of 2
 - Hint: check out function seq(...)
 - ▶ Subset the 3rd, 16th, and 25th elements of the vector
 - Subset those elements whose values are either smaller than 10, or greater than 40

```
# Q1
chr <- rep(letters, each = 3)
print(chr)
   [1] "a" "a" "a" "b" "b" "b" "c" "c" "c" "d" "d"

        US 327
## 1
```

Workflow in R

► Usual workflow for data anlaysis (Grolemund and Wickham 2016):

Program

► Tidyverse is a collection of packages designed for data science with unified grammar and data structures

- ► Tidyverse is a collection of packages designed for data science with unified grammar and data structures
- Tidy data:

- ► Tidyverse is a collection of packages designed for data science with unified grammar and data structures
- Tidy data:
 - Each variable must have its own column

- ► Tidyverse is a collection of packages designed for data science with unified grammar and data structures
- Tidy data:
 - Each variable must have its own column
 - Each observation must have its own row

- ► Tidyverse is a collection of packages designed for data science with unified grammar and data structures
- Tidy data:
 - Each variable must have its own column
 - Each observation must have its own row
 - ► Each value must have its own cell

► To install Tidyverse package, run:

```
install.packages("tidyverse")
```

▶ To load a package, run (usually at the top of your R document):

```
library(tidyverse)
```

Importing data in R

```
# Load package
library(tidyverse)
# Load econ.csv
econ <- read csv("http://staff.washington.edu/kpleung/vis/data/e
## Parsed with column specification:
## cols(
##
    country = col_character(),
## GWn = col_double(),
## year = col_double(),
    gdpPercap = col_double()
##
## )
# tibble (tbl) is a special class of data frame
class(econ)
## [1] "spec_tbl_df" "tbl_df"
                                   "tbl"
   [4] "data.frame"
```

Importing data in R

```
## # A tibble: 6 x 4
## country GWn year gdpPercap
##
    <chr> <dbl> <dbl>
                           <dbl>
## 1 Afghanistan 700 1983 863.
## 2 Afghanistan
               700 1985 819.
## 3 Afghanistan
               700 1991 601.
## 4 Albania
               339 2000 2962.
## 5 Algeria
               615 1967 1824.
## 6 Algeria
               615 1968
                           1977.
```

Basic data wrangling: count()

Count number of rows in each group:

```
econ %>%
count(country)
```

```
## # A tibble: 146 x 2
##
     country
                                n
##
     <chr>
                            <int>
   1 Afghanistan
##
##
   2 Albania
##
   3 Algeria
                                5
##
   4 Angola
   5 Argentina
##
                                5
##
   6 Australia
##
   7 Austria
## 8 Bahrain
##
   9 Bangladesh
## 10 Belarus (Byelorussia)
## # ... with 136 more rows
```

Basic data wrangling: %>%

- What is %>% ("pipe")?
 - x %>% fun(y) is equivalent to fun(x, y)
 - Its advantage will be apparent when you perform numerous steps of manipulation

```
count(econ, country) # Equivalent to econ %>% count(country)
```

```
## # A tibble: 146 x 2
##
      country
                                 n
      <chr>>
##
                             <int>
   1 Afghanistan
                                 3
##
    2 Albania
##
                                 1
    3 Algeria
##
                                 5
##
    4 Angola
    5 Argentina
##
##
    6 Australia
                                 3
   7 Austria
##
                                 9
## 8 Bahrain
## 9 Bangladesh
## 10 Belarus (Byelorussia)
## # ... with 136 more rows
```

Basic data wrangling: arrange()

Order rows by values of column(s) from low to high:

```
econ %>%
  count(country) %>%
  arrange(n) # Rather than: arrange(count(econ, country), n)
## # A tibble: 146 x 2
##
      country
                                   n
      <chr>>
##
                               <int>
##
    1 Albania
    2 Belarus (Byelorussia)
##
    3 Cambodia (Kampuchea)
##
##
    4 Central African Republic
    5 Chile
##
##
    6 China
    7 Dominican Republic
##
    8 Estonia
##
##
    9 Gabon
## 10 Ghana
## # ... with 136 more rows
```

Basic data wrangling: arrange()

Order rows by values of column(s) from high to low:

```
econ %>%
  count(country) %>%
  arrange(desc(n))
## # A tibble: 146 x 2
##
      country
                                    n
      <chr>>
##
                                <int>
##
    1 United States of America
                                  112
    2 Mexico
                                   10
##
##
    3 Austria
##
    4 Uruguay
    5 Philippines
                                    8
##
##
    6 Denmark
##
   7 Norway
## 8 Portugal
##
    9 Trinidad and Tobago
## 10 Venezuela
## # ... with 136 more rows
```

Basic data wrangling: filter()

Extract rows that meet logical criteria:

Basic data wrangling: filter()

Extract rows that meet **multiple** logical criteria:

```
econ %>%
 filter(
   country == "Brazil" | country == "Russia (Soviet Union)" |
   country == "India" | country == "China"
## # A tibble: 9 x 4
## country
                           GWn year gdpPercap
                         <dbl> <dbl>
##
    <chr>>
                                        <dbl>
## 1 Brazil
                           140 1954 1848.
## 2 Brazil
                           140 1989 5224.
## 3 Brazil
                           140 2002 5481.
## 4 China
                           710 1996
                                        2892.
## 5 India
                           750 1943 698.
## 6 India
                           750 1961
                                        758.
## 7 India
                           750 1992 1350.
## 8 Russia (Soviet Union)
                                        6536.
                           365 1982
## 9 Russia (Soviet Union)
                          365 2005
                                        7269.
```

Basic data wrangling: filter()

Alternatively:

```
econ %>%
 filter(country %in% c("Brazil", "Russia (Soviet Union)", "India", "China"))
## # A tibble: 9 x 4
##
                            GWn year gdpPercap
    country
##
    <chr>>
                          <dbl> <dbl>
                                         <dbl>
## 1 Brazil
                            140 1954
                                         1848.
## 2 Brazil
                            140 1989 5224.
## 3 Brazil
                            140 2002
                                          5481.
## 4 China
                            710 1996
                                          2892.
## 5 India
                            750 1943 698.
## 6 India
                            750 1961
                                          758.
## 7 India
                            750 1992
                                         1350.
## 8 Russia (Soviet Union)
                            365 1982
                                          6536.
## 9 Russia (Soviet Union)
                            365
                                 2005
                                          7269.
```

Basic data wrangling: select()

Extract columns (variables):

```
econ %>%
select(country, year, gdpPercap)
```

```
## # A tibble: 557 x 3
##
     country year gdpPercap
##
     <chr>
               <dbl>
                        <dbl>
   1 Afghanistan 1983
                         863.
##
##
   2 Afghanistan
               1985
                         819.
##
   3 Afghanistan 1991
                         601.
  4 Albania
                2000
                        2962.
##
##
   5 Algeria
               1967
                        1824.
##
   6 Algeria
                1968
                        1977.
  7 Algeria
                1977
                        2759.
##
##
   8 Algeria
                1986
                        3301.
   9 Algeria
                2006
                        3386.
##
## 10 Angola
                1953
                        1126.
## # ... with 547 more rows
```

Basic data wrangling: filter() & select()

Filter USA observations from 2000 to 2010 with year and gdpPercap as the only variables:

```
## # A tibble: 11 x 2
##
      year gdpPercap
##
     <dbl>
            <dbl>
      2000 28702.
##
   1
##
   2 2001 28726.
##
   3 2002 28977.
##
      2003 29459.
##
   5 2004 30200.
      2005
             30842.
##
##
   7
      2006
             31358.
##
      2007
             31655.
   8
             31251.
##
      2008
## 10
      2009
             29899.
## 11
      2010
             30491.
```

Basic data wrangling: summarize()

Compute table of summaries:

```
USAdata %>%
summarize(avg_gdpPercap = mean(gdpPercap))
```

```
## # A tibble: 1 x 1
## avg_gdpPercap
## <dbl>
## 1 30142.
```

What if we want to calculate the average GDP per capita for all countries in our data set?

Basic data wrangling: group_by() & summarize()

- Create a grouped version of the table with group_by()
 - Subsequent functions will manipulate each group separately

```
econ %>%
 group_by(country) %>%
  summarize(avg_gdpPercap = mean(gdpPercap)) %>%
 arrange(desc(avg_gdpPercap))
## `summarise()` ungrouping output (override with `.groups` argument)
## # A tibble: 146 x 2
##
     country
                              avg gdpPercap
     <chr>>
                                      <dbl>
##
## 1 Qatar
                                     39157.
   2 Kuwait
                                     16288.
##
   3 German Federal Republic
                                     15739.
##
##
   4 Norway
                                     14846.
## 5 Treland
                                     14353.
   6 Belarus (Byelorussia)
                                   13659.
##
## 7 United States of America
                                13623.
## 8 United Arab Emirates
                                   12812.
##
   9 Belgium
                                     12053.
## 10 Austria
                                     11794.
## # ... with 136 more rows
```

Basic data wrangling: more summarize()

What if we want to know the numbers of distinct countries and years in the data set?

```
econ %>%
  summarize_at(c("country", "year"), n_distinct)
```

```
## # A tibble: 1 x 2
## country year
## <int> <int>
## 1 146 111
```

Basic data wrangling: mutate()

Compute new columns (variables):

```
econ %>%
  mutate(
   id = row_number(),
   decade = year %/% 10 * 10
) %>%
  select(id, country, GWn, year, decade, gdpPercap)
```

```
## # A tibble: 557 x 6
##
         id country
                          GWn
                               year decade gdpPercap
##
